

Enterprise Access to Claude.ai & RDF Studio for Knowledge-Driven Analytics

A partnership proposal for Architecture and IT Services

Program	Knowledge-Driven Analytics (KDA) Capability
Pilot deliverable	HR Advisory 360 Semantic Intelligence Agent (design-time proof of capability)
Sponsoring organization	Enterprise Analytics
Partners	IT Architecture & Review Board IT Services HR Technology Steering Committee Enterprise Tooling Procurement
Requested tooling	Claude.ai (Enterprise / Team workspace) — semantic reasoning, mapping drafts and impact simulation RDF Studio — visual ontology / taxonomy modeling, SKOS scheme design and schema governance
Requested window	90-day evaluation, 3–5 seats, design-time only

Our intent, in brief

This proposal **does not change who owns production, platforms, or standards**. Architecture continues to set enterprise standards. IT Services continues to own production, security, and operations. Existing CI/CD, change management, and data governance stay exactly as they are.

Enterprise Analytics is asking for two **design-time** tools and a working partnership with Architecture and IT to prove one bounded use case. If the pilot doesn't meet success criteria we agree on together, we stop — with nothing in production to unwind.

1. Executive Summary

Enterprise Analytics proposes a 90-day, design-time proof of capability for **Knowledge-Driven Analytics (KDA)**.

In most enterprises, business meaning — definitions, policies, job frameworks — ends up spread across operational tables and pipeline logic. That makes it slow to change and hard to explain, and it often means business-rule changes arrive on IT's backlog as pipeline work. KDA treats knowledge as a **business-owned asset**: Enterprise Analytics works with business owners to formalize their definitions, policies, and taxonomies into governed semantic models, and hands IT stable, tested assets to run.

To do this well, the modeling team needs a design-time workbench:

- **RDF Studio** — the visual modeling and governance environment for enterprise taxonomies, domain schemas, and canonical graphs.
- **Claude.ai** — an assistant that drafts SKOS concept hierarchies, cross-schema IRI mappings, and SHACL validation shapes, and helps simulate change impact. Every Claude-drafted artifact is reviewed by a person before it is used.

The proving ground is the **HR Advisory 360 Agent**, an analytics-driven assistant for multi-jurisdiction, policy-constrained workforce questions that today's dashboards and vector search (RAG) struggle to answer reliably.

2. Strategic Context: Business First, Architecture and IT as Partners

Enterprise Analytics already has trusted working relationships with business leaders. KDA builds on that: the business owns its rules and terminology directly, Enterprise Analytics makes that meaning computable, Architecture sets the guardrails, and IT Services runs the result. Figure 1 shows the operating model.

Why this capability belongs in Enterprise Analytics

- **Closest to the meaning.** Enterprise Analytics already works with HR leaders on definitions, metrics, and policy questions. Capturing meaning correctly starts with those conversations.
- **Already a consumer of IT's platforms.** Enterprise Analytics builds on the data products IT provides; a semantic layer is a natural extension of that role, not a new platform.
- **Design-time, not run-time.** The work is modeling and validation in a sandbox. Anything that reaches production goes through IT's existing promotion path.
- **Frees IT for platform work.** When business rules live in governed models rather than pipeline code, routine policy changes stop arriving as pipeline tickets.

Figure 1 · Operating model: business first, Architecture and IT as partners

Business first. Architecture and IT as partners.

Knowledge-Driven Analytics operating model — who owns what, and how business meaning flows to production.

Why Enterprise Analytics? It sits at the seam — close enough to the business to capture meaning correctly, disciplined enough to hand IT stable, tested, standards-conformant models. Business-rule changes stop landing on IT's pipeline backlog, and Architecture keeps setting the rules of the road.

The business decides what is true; Enterprise Analytics makes it computable and governed; IT Services runs it reliably. Architecture provides guardrails at every step — not only a gate at the end.

What stays the same

Area	Unchanged under this proposal
Enterprise standards	Architecture and the Architecture Review Board (ARB) remain the authority for IRI conventions, reference patterns, and integration standards.
Production & platforms	IT Services remains the sole owner of production systems, endpoints, security, SSO, and operations.
Change management	All artifacts are promoted through the existing CI/CD pipeline, regression tests, and Git peer review — no exceptions for generated code.
Data governance	Existing data classification and privacy rules apply. Production PII/PHI is not used in the modeling environment.

Expected business impact: HR Advisory 360 pilot

The outcomes below are **pilot hypotheses**. We will baseline them with IT and HR in Phase 1 and report actual results at the Phase 4 readout.

Dimension	Today	KDA approach	Pilot target (to be measured)
Cross-system analysis	Analysts reconcile Workday, ServiceNow, and regional policy documents by hand.	A unified semantic layer connects employee profiles to business rules and job frameworks.	Up to 70% faster time-to-insight for complex HR policy questions.
Absorbing source schema changes	Vendor schema changes can ripple into pipelines and dashboards, creating unplanned work for IT.	Virtualized semantic mappings absorb source changes in one governed place.	No downstream report or agent changes needed for simulated quarterly SaaS upgrades.
Compliance & traceability	It can be hard to show why a specific policy path was recommended.	Explicit semantic graphs with PROV-O provenance trace each rule that fired.	Audit-ready lineage for every pilot answer.

3. The Dual Tooling Stack: Complementary Roles

RDF Studio and Claude.ai play distinct, non-overlapping roles in the design workflow. Neither runs in production.

RDF Studio — the visual modeler	Claude.ai — the drafting assistant
Visual taxonomy and ontology design	Drafts OWL axioms from written business policy
Graphical view of entity classes and relationships	Generates declarative RML / SPARQL mapping drafts

RDF Studio — the visual modeler	Claude.ai — the drafting assistant
Central repository for enterprise vocabularies	Produces SHACL shapes for data-quality checks
Canonical schema inspection and versioning	Simulates change impact and flags breaking diffs

- **RDF Studio (the canvas)** is where analysts and business data stewards structure the HR domain together: jobs, locations, benefit structures, and compliance classes.
- **Claude.ai (the co-pilot)** removes syntax friction. It turns policy manuals into candidate SKOS concepts, drafts mappings between source columns and model IRIs, and writes SHACL constraints. **People review and approve every draft**; Claude never writes to a shared repository or system on its own.

4. How We Deliver Together

Figure 2 traces a single change through the HR Advisory 360 lifecycle. The business starts it, Enterprise Analytics shapes and validates it, Architecture engages both up front and before promotion, and IT Services promotes and runs it through the processes it already owns.

Figure 2 · How we deliver together: one change through the HR Advisory 360 lifecycle

How we deliver together

One change through the HR Advisory 360 lifecycle — the business starts it, Enterprise Analytics shapes it, Architecture and IT make it safe to run.

Architecture engages twice — up front to set standards, and before promotion to confirm conformance. IT owns everything right of the dashed line; nothing crosses it without CI/CD and peer review.

Everything left of the dashed line happens in the design-time sandbox. Nothing crosses into IT-owned production without CI/CD, regression testing, and peer review.

4.1 Business vocabulary and taxonomy harmonization

- Enterprise Analytics uses RDF Studio to establish SKOS-XL concept schemes for corporate leveling, roles, and competencies — using the naming and IRI conventions agreed with Architecture.
- Claude.ai reads external frameworks (e.g., O*NET, standard labor codes) alongside corporate job descriptions and proposes alignment and hierarchy candidates. Analysts review them before importing into RDF Studio.

4.2 A virtualized semantic layer over existing systems

- Workday and ServiceNow continue to expose data through the REST endpoints and SQL views IT already manages.
- Rather than building another physical warehouse, Enterprise Analytics designs a virtualized graph layer on top of those interfaces.
- Claude.ai drafts declarative schema-to-ontology mappings (RML, SPARQL CONSTRUCT). If a field name changes in Workday, the mapping is updated in one place and downstream reports and agent APIs keep working — reducing ripple-effect work for IT.

4.3 Quality assurance before anything is handed off

- Quality is checked upstream, before data reaches any consumer.
- Analysts express business constraints (e.g., “Senior Advisory roles require Grade 12+ and jurisdictional licensing in California”), Claude drafts the matching SHACL shapes, and the shapes are validated in RDF Studio with logged results for every test scenario.
- **Impact simulation:** when HR changes a sabbatical or retention policy, the team runs the change against baseline queries to surface unintended downstream effects before anyone is asked to sign off.

4.4 Where Architecture and IT engage

When	Architecture	IT Services
Weeks 1–3 (setup)	Working session to agree IRI, prefix, naming, and reference-pattern conventions.	SSO / RBAC for 3–5 seats; sandbox and read-only metadata / source-view access.
Weeks 4–7 (modeling)	Optional mid-point check-in on model structure.	Informed; no new requests expected.
Weeks 8–10 (validation)	Conformance review of models and mappings.	Guidance on onboarding artifacts to existing CI/CD and Git review.
Weeks 11–12 (readout)	Co-present results; shared recommendation.	Co-present results; shared go / no-go decision.

5. Roles, Responsibilities & Safeguards

Figure 3 sets out who does what across the lifecycle. Enterprise Analytics carries the semantic work, but accountability for business meaning, architecture standards, and production stays with the teams that hold it today. Figure 4 shows the boundary between the design-time sandbox and IT-owned production.

What this means for IT Services

- **Fewer business-rule changes in pipelines.** Routine policy and terminology changes are handled in governed semantic models with business owners, so they arrive on IT's backlog less often.
- **Stable consumption endpoints.** IT receives IRI-grounded semantic endpoints for downstream applications, insulated from backend SaaS schema changes.
- **No direct production exposure.** Claude.ai and RDF Studio are design-time tools used only in analytical staging and modeling sandboxes. Nothing they help produce reaches production without passing standard CI/CD regression tests and Git-based peer review.
- **Enterprise security standards:**
 - Claude.ai Enterprise terms: customer inputs and outputs are not used to train models by default.
 - Role-based access control managed through corporate Okta / SAML SSO.
 - Work uses conceptual schemas, metadata, and anonymized synthetic test sets only; production PII/PHI is excluded from the modeling environment.

Figure 3 · Who does what (RACI)

Who does what

Responsibilities across the Knowledge-Driven Analytics lifecycle. The business is accountable for meaning; IT is accountable for production; Enterprise Analytics does the semantic work in between.

ACTIVITY	BUSINESS	ENTERPRISE ANALYTICS	ARCHITECTURE	IT SERVICES
Define business terms, policies & rules	A / R	C	I	I
Model taxonomies & ontologies in RDF Studio	C	A / R	C	I
Draft axioms, mappings & SHACL with Claude.ai	I	A / R	C	I
Set IRI, prefix & reference-pattern standards	I	C	A / R	C
Validate quality & simulate change impact	C	A / R	I	C
Architecture conformance review (ARB)	I	R	A	C
Promote through CI/CD, regression & peer review	I	R	C	A
Operate endpoints, security, SSO & access	I	C	C	A / R
Accept the business outcome	A	R	I	I

A

 Accountable — owns the decision

R

 Responsible — does the work

C

 Consulted — two-way input

I

 Informed — kept current

Reading the matrix: Enterprise Analytics carries the semantic work, but never holds accountability for business meaning, architecture standards, or production — those stay with the teams who own them today.

Accountability for business meaning, architecture standards, and production stays with the teams that own them today. Enterprise Analytics is responsible for the semantic work in between.

Figure 4 · Design-time tools, run-time discipline

Design-time tools, run-time discipline

Claude.ai and RDF Studio stay in the Enterprise Analytics sandbox. IT keeps control of production — every model crosses the same gate as any other code.

What this asks of IT: provision a sandbox and read-only metadata access. **What IT gets back:** tested, reviewed semantic assets and fewer business-rule changes landing in pipelines.

Claude.ai and RDF Studio stay in the Enterprise Analytics sandbox and work only with metadata and synthetic data. A shared promotion gate protects IT-owned production.

6. Pilot Implementation & Resource Request

Enterprise Analytics requests approval for a **90-day evaluation window** to establish the HR Advisory 360 proof of capability.

Phase	Weeks	Enterprise Analytics delivers	Architecture & IT involvement
1. Environment & setup	1–3	Provision 3–5 Claude.ai Enterprise seats and RDF Studio; agree standard prefixes; baseline the success measures.	IT: SSO / RBAC and sandbox. Architecture: conventions working session.
2. HR 360 semantic modeling	4–7	Build the core HR taxonomy in RDF Studio; draft virtualized mappings and policy axioms with Claude.ai, all peer-reviewed.	IT: read-only metadata access. Architecture: optional check-in.
3. Validation & agent testing	8–10	Run SHACL validation suites and drift / impact simulations against mock HR advisory queries.	Architecture: conformance review. IT: CI/CD onboarding guidance.
4. Readout & architecture review	11–12	Present results to IT Services, the ARB, and the HR Steering Committee, showing pipeline stability and analytical precision.	Joint readout and shared continue / adjust / stop decision.

Success criteria (to be confirmed jointly in Phase 1)

- Measured reduction in time-to-answer for an agreed set of complex HR policy questions, against a Phase 1 baseline.
- Simulated source schema changes absorbed in the mapping layer with no downstream report or agent changes.
- 100% of promoted artifacts pass CI/CD regression tests and Git peer review.
- Architecture conformance sign-off on the pilot models and mappings.
- Zero production PII/PHI in the modeling environment for the duration of the pilot.

7. What We're Asking — and Where We Want Your Input

Requests

- **Architecture:** a working session in weeks 1–3 to agree conventions, a conformance review in Phase 3, and a shared voice in the readout recommendation.
- **IT Services:** SSO / RBAC for 3–5 seats, a modeling sandbox with read-only metadata access, and guidance on onboarding artifacts into the existing CI/CD and Git review process.
- **Procurement:** 90-day evaluation licensing for Claude.ai (Enterprise) and RDF Studio.

Open questions we'd value your guidance on

1. Which IRI namespace and prefix conventions should the pilot adopt, or should we draft a proposal for the ARB to review?
2. What data classification applies to model metadata and synthetic test sets?
3. Which repository and CI/CD pipeline should pilot artifacts use?
4. Are there additional review points Architecture or IT would like built into the 12-week plan?

Our commitment

We will build on the standards and processes Architecture and IT already own, keep all work in the design-time sandbox, and make every decision about production jointly. The goal is shared: governed, explainable answers for the business, and less unplanned work for IT.
